Changing the face of fever of unknown origin in Egypt: a single hospital study

Dear Editor,

Infections remain the most frequent cause of fever of unknown origin (FUO) in developing countries. Some cases of fever remain a mystery and patients are discharged without knowing the cause. Prehospital healthcare facilities vary between countries, and even within the same country. FUO was first described in 1961 by Petersdorf and Beeson when they established the three criteria that define FUO: a minimum measured temperature of 38.3°C , febrile states occurring on several occasions over a period of at least three weeks, and a minimum of one week of investigations being required.¹ The modern definition of FUO is based on modifications of these criteria taking into account four specific patient subtypes: classic, nosocomial, immunodeficient (neutropenic), and HIV-associated FUO.^{2,3}

We outlined changes in causes of classic FUO according to the latest definition and compare the causes with those of a previous study conducted at the same hospital in 1974.⁴ We retrospectively reviewed 374 adult patients with FUO admitted to the Abbassia Fever Hospital under the definition outlined by Durack and Street (1991).⁵ Data were obtained from admission files. The patient population comprised 217 (58%) male patients, with a mean age of 40.2 ± 14.5 years. Further, 240 patients (64.2%) lived in urban areas, while 134 (35.8%) lived in rural areas.

A continuous pattern of fever was found in 211 patients (58.3%), while 58 patients (16%) presented with a remittent pattern, and 87 patients (23.2%) showed intermittent fever symptoms. Six patients (1.6%) had relapsing fever.

Blood cultures grew Gram-negative organisms in only nine cases (2.4%) and Gram-positive in eight cases (2.1%). Also, in urine cultures Gram-negative organisms were dominant including *E. coli*, *Klebsiella* and *Enterobacter* while Gram-positive cocci were only *S. aureus*.

With regard to the final diagnosis, 248 patients (66.3%) were diagnosed with an infection etiology for FUO. Of these patients, 46 had cytomegalovirus infection (CMV). Among the non-infection patients, 49 (13.1%) were categorized in the miscellaneous group, and 29 (7.8%) were discharged without a final diagnosis (Table 1).

Table 1 – Final diagnosis in the studied population.

Final diagnosis	Frequency	Percent
Infection	248	66.3
CMV	46	12.3
UTI	39	10.4
Bronchitis	35	9.4
Pneumonia	26	7.0
Typhoid fever	23	6.1
Brucellosis	22	5.9
Septicemia	13	3.5
Tuberculosis	11	2.9
Infective endocarditis	8	2.1
Chronic hepatitis	6	1.6
Other infections ^a	19	5.1
Collagen diseases	27	7.2
Rheumatoid arthritis	13	3.5
SLE	7	1.9
Adult Still's disease	6	1.6
Rheumatic fever	1	0.3
Malignancy	27	7.2
Blood malignancy	20	3.5
Solid malignancy	7	1.9
Miscellaneous ^b	43	11.5
IBD	10	2.6
Drug fever	9	2.4
Behcet's disease	8	2.1
FMF	6	1.6
Undiagnosed	29	7.8
Total	374	100.0

^a Other infections: EBV (4 patients), enterocolitis (3 patients), pelvic abscess (3 patients), cholecystitis (2 patients), liver abscess (2 patients), pyelonephritis (2 patients), Appendicular abscess (1 patient), encephalitis (1 patient) and gluteal abscess (1 patient).

^b Miscellaneous: thyrotoxicosis (5 patients), liver cell failure (4 patient) and portal vein thrombosis (1 patient).

Comparing the findings of the present study with a similar study conducted in 1974 that examined 129 patients with FUO in the same hospital,⁴ we found that infections still represent the main cause of FUO in Egypt (66.3% vs. 60% in 1974); however, the percentage of undiagnosed cases has dropped from 12% to 7.8%. *Salmonella* infection was diagnosed in 23 of 248 cases of infection, while brucellosis accounted for 22 cases.

Infections remain the predominant cause of FUO in Egypt; however, the causative agents have changed over the last 40 years. The proportion of undiagnosed cases of FUO seems to be lower than what it was in the past due to advances in diagnostic technologies. Finally, clinicians must be aware that the etiology of FUO varies across demographics, geography, and time. Accordingly, reporting local cases is important in informing clinicians about the epidemiologic pattern.

Authorship

Prof Mohamed Fawzy Montasser: Chosen the research idea and revised the results Ass. Prof Nadia Abdelaaty: follow up data collection, revise the results and wrote the manuscript. Dr Iman Montasser: data analysis, wrote and submitted the manuscript, Dr Ahmed El Khouly: Data collection, statistical analysis.

Ethics statement

This study was carried out after approval of Research and Ethics Committee of Ain Shams University, Cairo, Egypt in accordance with local research governance requirements. All human studies have been approved by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki and all subsequent revisions.

Sources of funding

This research received no specific grant from any funding agency in the public, commercial or not-for-profit sectors.

Conflicts of interest

There are no financial or other relations that could lead to a conflict of interest.
